

1.The system is used to calculate employee salary based on hours worked, hourly rate, and deduction such as tax. The user first enter employee details, then program multiplier hours worked per day to find gross salary. After that it calculate tax deduction and subtract them from gross salary.

The flow chart is used to show step by step process using symbols like input/ output, process and decision.

Pseudocode is also used to the same logic one simple terms for clear drawings which are simple.

2. Flow chart symbol is a visual shape used to represent step in a process, it shows where a program must make a choice.

For example, in a login, the decision symbol check if the password is correct. If yes the user is allowed to continue to log in.

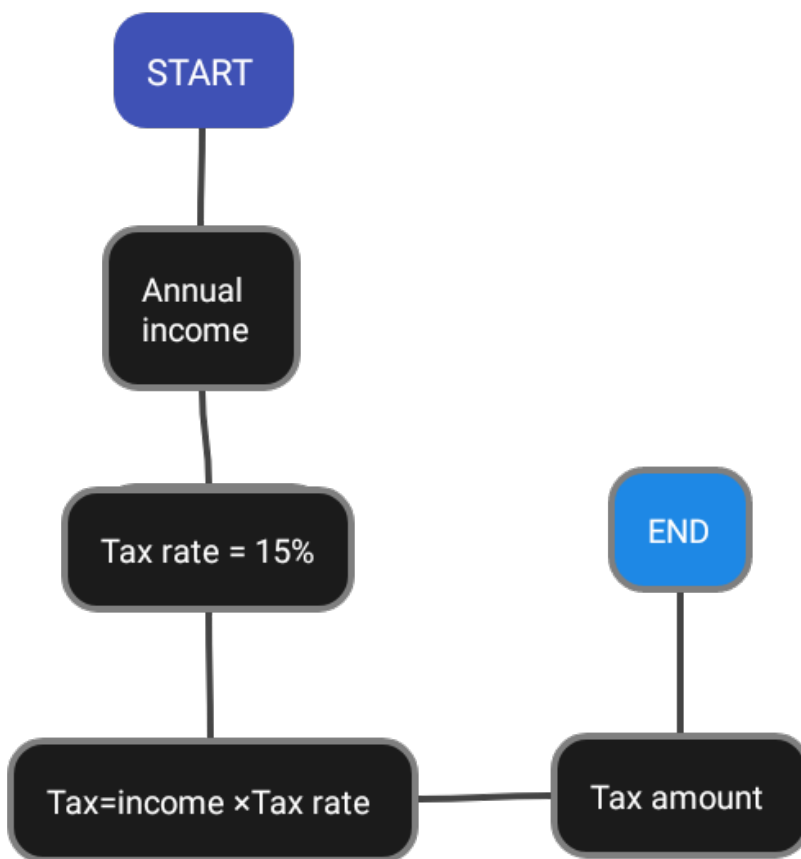

3.I designed a flow chart that take user income as input,

calculate tax based on a fixed rate of tax, and display final amount after deductions. This improved my understand of how programming logic is planned visually before coding.

4. A decision based for a login check process helps for verify user credentials before getting access. The process starts by entering a username and password. The system then check whether entered information matches the stored

records. If the details are incorrect the system displays an error message and ask user to re enter the password and username

3. Calculate tax

4. Login test
